Lingering Questions

Bernanke: “QE works in practice but not in theory”

Lingering Questions

Bernanke: “QE works in practice but not in theory”

- Develop a GE model which takes seriously limits to arbitrage
 - ▶ Derive **theoretical conditions** under which QE works
 - ▶ **Quantify** the aggregate effects of QE

Lingering Questions

Bernanke: “QE works in practice but not in theory”

- Develop a GE model which takes seriously limits to arbitrage
 - ▶ Derive **theoretical conditions** under which QE works
 - ▶ **Quantify** the aggregate effects of QE
- Bond market imperfections play a role in the transmission of **conventional** monetary policy

Lingering Questions

Bernanke: “QE works in practice but not in theory”

- Develop a GE model which takes seriously limits to arbitrage
 - ▶ Derive **theoretical conditions** under which QE works
 - ▶ **Quantify** the aggregate effects of QE
- Bond market imperfections play a role in the transmission of **conventional** monetary policy
- Crucial for designing monetary policy going forward

Model Overview

- Ingredients:
 - ▶ Households do not have full access to bond markets
 - ▶ Key investors have imperfect risk-bearing capacity

Model Overview

- Ingredients:
 - ▶ Households do not have full access to bond markets
 - ▶ Key investors have imperfect risk-bearing capacity
 - ▶ \implies endogenous degree of segmentation/preferred habitat

Model Overview

- Ingredients:
 - ▶ Households do not have full access to bond markets
 - ▶ Key investors have imperfect risk-bearing capacity
 - ▶ \implies endogenous degree of segmentation/preferred habitat
- Dual equilibrating role of the yield curve:
 1. **Macro channel:** Intertemporal decisions of long-lived agents
 2. **Finance channel:** Short-run portfolio demands from investors

Model Overview

- Ingredients:
 - ▶ Households do not have full access to bond markets
 - ▶ Key investors have imperfect risk-bearing capacity
 - ▶ \implies endogenous degree of segmentation/preferred habitat
- Dual equilibrating role of the yield curve:
 1. **Macro channel:** Intertemporal decisions of long-lived agents
 2. **Finance channel:** Short-run portfolio demands from investors
- Monetary policy works through both channels

Preview: Implications

- Theoretical results:
 - ▶ QE works if and only if bond markets are disrupted

Preview: Implications

- Theoretical results:
 - ▶ QE works if and only if bond markets are disrupted
 - ▶ Declining risk-bearing capacity mitigates the transmission of conventional policy (and FG)

Preview: Implications

- Theoretical results:
 - ▶ QE works if and only if bond markets are disrupted
 - ▶ Declining risk-bearing capacity mitigates the transmission of conventional policy (and FG)
- Quantitative results:
 - ▶ $QE \approx 50\text{-}75$ b.p. cut in policy rate in normal times

Preview: Implications

- Theoretical results:
 - ▶ QE works if and only if bond markets are disrupted
 - ▶ Declining risk-bearing capacity mitigates the transmission of conventional policy (and FG)
- Quantitative results:
 - ▶ $QE \approx 50-75$ b.p. cut in policy rate in normal times
 - ▶ Conventional policy during crisis $\approx 80\%$ as effective as in normal times

Preview: Implications

- Theoretical results:
 - ▶ QE works if and only if bond markets are disrupted
 - ▶ Declining risk-bearing capacity mitigates the transmission of conventional policy (and FG)
- Quantitative results:
 - ▶ $QE \approx 50-75$ b.p. cut in policy rate in normal times
 - ▶ Conventional policy during crisis $\approx 80\%$ as effective as in normal times
- Designing policy going forward:
 - ▶ Conventional policy: more aggressive in financial crises

 - ▶ Conventional policy during crisis $\approx 80\%$ as effective as in normal times
- Designing policy going forward:
 - ▶ Conventional policy: more aggressive in financial crises
 - ▶ QE rule can be stabilizing

Literature Contributions

- “Preferred habitat” as a key channel for understanding bond markets
 - ▶ D’Amico and King (2013), Hamilton and Wu (2012), Greenwood and Vayanos (2014), Gorodnichenko and Ray (2017), Greenwood and Vissing-Jorgensen (2018)
- Few formal models
 - ▶ Vayanos and Vila (2009)
- QE in general equilibrium: Market segmentation vs. forward guidance
 - ▶ Gertler and Karadi (2013), Chen et al (2012), Carlstrom et al (2017), Christensen and Rudebusch (2012), Bauer and Rudebusch (2014), Bhattarai et al (2015)
- Frictions and expected future policy
 - ▶ McKay et al (2016), Farhi and Werning (2017), Gabaix (2016), Angeletos and Lian (2018)

New Keynesian Preferred Habitat Framework

- Time $t \in [0, \infty)$ is continuous. Consumption and production:
 - ▶ Infinitely-lived **households** work and consume
 - ▶ **Firms** produce using labor, face price frictions

New Keynesian Preferred Habitat Framework

- Time $t \in [0, \infty)$ is continuous. Consumption and production:
 - ▶ Infinitely-lived **households** work and consume
 - ▶ **Firms** produce using labor, face price frictions
- Bonds with maturity $\tau \in [0, T]$. Bond market investors:
 - ▶ HHs save and borrow through a passive **index fund**
 - ▶ **Habitat investors** with maturity-specific demand
 - ▶ Short-lived **arbitrageurs** render term structure arbitrage-free

New Keynesian Preferred Habitat Framework

- Time $t \in [0, \infty)$ is continuous. Consumption and production:
 - ▶ Infinitely-lived **households** work and consume
 - ▶ **Firms** produce using labor, face price frictions
- Bonds with maturity $\tau \in [0, T]$. Bond market investors:
 - ▶ HHs save and borrow through a passive **index fund**
 - ▶ **Habitat investors** with maturity-specific demand
 - ▶ Short-lived **arbitrageurs** render term structure arbitrage-free
- Government:
 - ▶ **Central bank** sets the short nominal rate (and conducts QE)
 - ▶ Lump-sum taxes/transfers from investors to HHs

Aggregate Dynamics

- Modification of a benchmark NK model ($\pi_t \equiv 0$):

$$dx_t = \varsigma^{-1} (r_t - \bar{r}) dt \quad (\text{IS})$$

Aggregate Dynamics

- Modification of a benchmark NK model ($\pi_t \equiv 0$):

$$dx_t = \varsigma^{-1} (r_t - \bar{r}) dt \quad (\text{IS})$$

Aggregate Dynamics

- Modification of a benchmark NK model ($\pi_t \equiv 0$):

$$d\mathbf{x}_t = \varsigma^{-1} (r_t - \bar{r}) dt \quad (\text{IS})$$

Aggregate Dynamics

Solving the Model

- Equilibrium affine term structure

$$-\log P_{t,\tau} = A_r(\tau)r_t + C(\tau)$$

Solving the Model

- Equilibrium affine term structure

$$-\log P_{t,\tau} = A_r(\tau)r_t + C(\tau)$$

- Effective borrowing rate:

$$\tilde{r}_t = \underbrace{\left[\int_0^T \frac{\eta(\tau)}{\tau} A_r(\tau) d\tau \right]}_{\equiv \hat{A}_r} r_t + \underbrace{\left[\int_0^T \frac{\eta(\tau)}{\tau} C(\tau) d\tau \right]}_{\equiv \hat{C}}$$

- Aggregate dynamics

$$dr_t = -\kappa_r(r_t - \phi_x x_t - r^*) dt + \sigma_r dB_{r,t}$$

$$dx_t = \varsigma^{-1} \left(\hat{A}_r r_t + \hat{C} - \bar{r} \right) dt$$

Solving the Model

- Equilibrium affine term structure

$$-\log P_{t,\tau} = A_r(\tau)r_t + C(\tau)$$

- Effective borrowing rate:

$$\tilde{r}_t = \underbrace{\left[\int_0^T \frac{\eta(\tau)}{\tau} A_r(\tau) d\tau \right]}_{\equiv \hat{A}_r} r_t + \underbrace{\left[\int_0^T \frac{\eta(\tau)}{\tau} C(\tau) d\tau \right]}_{\equiv \hat{C}}$$

- Aggregate dynamics

$$dr_t = -\kappa_r(r_t - \phi_x x_t - r^*) dt + \sigma_r dB_{r,t}$$

$$dx_t = \varsigma^{-1} \left(\hat{A}_r r_t + \hat{C} - \bar{r} \right) dt$$

Rational Expectations Dynamics

- Linear stochastic differential equation:

$$d\mathbf{Y}_t = -\Upsilon \left(\mathbf{Y}_t - \mathbf{Y}^{SS} \right) dt + \mathbf{S} d\mathbf{B}_t$$

$$\Upsilon = \begin{bmatrix} \kappa_r & -\kappa_r \phi_x \\ -\varsigma^{-1} \hat{A}_r & 0 \end{bmatrix}$$

Rational Expectations Dynamics

- Linear stochastic differential equation:

$$d\mathbf{Y}_t = -\Upsilon \left(\mathbf{Y}_t - \mathbf{Y}^{SS} \right) dt + \mathbf{S} d\mathbf{B}_t$$

$$\Upsilon = \begin{bmatrix} \kappa_r & -\kappa_r \phi_x \\ -\varsigma^{-1} \hat{A}_r & 0 \end{bmatrix}$$

- If determinacy conditions are met:

$$dr_t = -\lambda_1(r_t - r^{SS}) dt + \sigma_r dB_{r,t}$$

$$x_t = \omega_x(r_t - r^{SS})$$

Rational Expectations Dynamics

- Linear stochastic differential equation:

$$d\mathbf{Y}_t = -\Upsilon \left(\mathbf{Y}_t - \mathbf{Y}^{SS} \right) dt + \mathbf{S} d\mathbf{B}_t$$

$$\Upsilon = \begin{bmatrix} \kappa_r & -\kappa_r \phi_x \\ -\varsigma^{-1} \hat{A}_r & 0 \end{bmatrix}$$

- If determinacy conditions are met:

$$dr_t = -\lambda_1 (r_t - r^{SS}) dt + \sigma_r dB_{r,t}$$

$$x_t = \omega_x (r_t - r^{SS})$$

Rational Expectations Dynamics

- Linear stochastic differential equation:

$$d\mathbf{Y}_t = -\Upsilon \left(\mathbf{Y}_t - \mathbf{Y}^{SS} \right) dt + \mathbf{S} d\mathbf{B}_t$$

$$\Upsilon = \begin{bmatrix} \kappa_r & -\kappa_r \phi_x \\ -\varsigma^{-1} \hat{A}_r & 0 \end{bmatrix}$$

- If determinacy conditions are met:

$$dr_t = -\lambda_1(r_t - r^{SS}) dt + \sigma_r dB_{r,t}$$

$$x_t = \omega_x(r_t - r^{SS})$$

Dynamics and Output Growth Sensitivity

Notes: impulse response functions of the policy rate and output in response to a unit monetary shock, as equilibrium output growth sensitivity to the policy rate falls. Darker lines correspond to lower output growth sensitivity \hat{A}_r . [phase diagrams](#)

$$dr_t = -\lambda(r_t - r^{SS})dt + \sigma_r dB_{r,t}$$

- Optimality conditions:

$$\begin{aligned}\mu_{t,\tau} - r_t &= A_r(\tau)\zeta_t \\ \zeta_t &\equiv a\sigma_r^2 \int_0^T b_{t,\tau} A_r(\tau) d\tau\end{aligned}$$

- Non-zero excess expected returns required to compensate for riskier allocations

Arbitrageur Portfolio Choice

- Take as given equilibrium dynamics of the short rate

$$dr_t = -\lambda(r_t - r^{SS}) dt + \sigma_r dB_{r,t}$$

- Optimality conditions:

$$\begin{aligned}\mu_{t,\tau} - r_t &= A_r(\tau)\zeta_t \\ \zeta_t &\equiv a\sigma_r^2 \int_0^T b_{t,\tau} A_r(\tau) d\tau\end{aligned}$$

- Non-zero excess expected returns required to compensate for riskier allocations

Absorbing Demand Shocks

$$\frac{\mu_{t,\tau} - r_t}{A_r(\tau)} = a\sigma_r^2 \int_0^T b_{t,\tau} A_r(\tau) d\tau$$

- Assume PH demand shifter is constant: $\beta_{t,\tau} = \bar{\beta}(\tau)$
- In equilibrium, arbitrageur portfolio must satisfy

$$b_{t,\tau} = -\alpha(\tau)\tau(R_{t,\tau} - \bar{\beta}(\tau))$$

Absorbing Demand Shocks

$$\frac{\mu_{t,\tau} - r_t}{A_r(\tau)} = a\sigma_r^2 \int_0^T b_{t,\tau} A_r(\tau) d\tau$$

- Assume PH demand shifter is constant: $\beta_{t,\tau} = \bar{\beta}(\tau)$
- In equilibrium, arbitrageur portfolio must satisfy

$$\begin{aligned} b_{t,\tau} &= -\alpha(\tau)\tau(R_{t,\tau} - \bar{\beta}(\tau)) \\ &= \alpha(\tau)(A_r(\tau)r_t + C(\tau) + \tau\bar{\beta}(\tau)) \end{aligned}$$

Absorbing Demand Shocks

$$\frac{\mu_{t,\tau} - r_t}{A_r(\tau)} = a\sigma_r^2 \int_0^T b_{t,\tau} A_r(\tau) d\tau$$

- Assume PH demand shifter is constant: $\beta_{t,\tau} = \bar{\beta}(\tau)$
- In equilibrium, arbitrageur portfolio must satisfy

$$\begin{aligned} b_{t,\tau} &= -\alpha(\tau)\tau(R_{t,\tau} - \bar{\beta}(\tau)) \\ &= \alpha(\tau)(A_r(\tau)r_t + C(\tau) + \tau\bar{\beta}(\tau)) \end{aligned}$$

- Prices adjust to balance demand and optimality conditions
- \implies differential equation which solves affine coefficients

$$\hat{A}_r \equiv \int_0^T \frac{\eta(\tau)}{\tau} A_r(\tau) d\tau$$

Term Structure Equilibrium

Characterizing \hat{A}_r (Term Structure Sensitivity)

The equilibrium reversion rate λ and the sensitivity of the term structure to the policy rate \hat{A}_r are related as follows:

$$\hat{A}_r = g(\lambda) = \int_0^T \eta(\tau) f(\nu(\lambda)\tau) d\tau$$

where $f(x) = \frac{1-e^{-x}}{x}$ and $\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau)\tau^2 f(\nu(\lambda)\tau)^2 d\tau$

Term Structure Equilibrium

Characterizing \hat{A}_r (Term Structure Sensitivity)

The equilibrium reversion rate λ and the sensitivity of the term structure to the policy rate \hat{A}_r are related as follows:

$$\hat{A}_r = g(\lambda) = \int_0^T \eta(\tau) f(\nu(\lambda)\tau) d\tau$$

where $f(x) = \frac{1-e^{-x}}{x}$ and $\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau)\tau^2 f(\nu(\lambda)\tau)^2 d\tau$

Term Structure Equilibrium

Characterizing \hat{A}_r (Term Structure Sensitivity)

The equilibrium reversion rate λ and the sensitivity of the term structure to the policy rate \hat{A}_r are related as follows:

$$\hat{A}_r = g(\lambda) = \int_0^T \eta(\tau) f(\nu(\lambda)\tau) d\tau$$

where $f(x) = \frac{1-e^{-x}}{x}$ and $\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau)\tau^2 f(\nu(\lambda)\tau)^2 d\tau$

Term Structure Equilibrium

Characterizing \hat{A}_r (Term Structure Sensitivity)

The equilibrium reversion rate λ and the sensitivity of the term structure to the policy rate \hat{A}_r are related as follows:

$$\hat{A}_r = g(\lambda) = \int_0^T \eta(\tau) f(\nu(\lambda)\tau) d\tau$$

where $f(x) = \frac{1-e^{-x}}{x}$ and $\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau)\tau^2 f(\nu(\lambda)\tau)^2 d\tau$

Term Structure Equilibrium

Characterizing \hat{A}_r (Term Structure Sensitivity)

The equilibrium reversion rate λ and the sensitivity of the term structure to the policy rate \hat{A}_r are related as follows:

$$\hat{A}_r = g(\lambda) = \int_0^T \eta(\tau) f(\nu(\lambda)\tau) d\tau$$

where $f(x) = \frac{1-e^{-x}}{x}$ and $\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau)\tau^2 f(\nu(\lambda)\tau)^2 d\tau$

Risk-Adjusted Reversion Rate

$$\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau) \tau^2 f(\nu(\lambda)_\tau)^2 d\tau$$

- ν vs. λ : Consider a shock to short rate at time t

Risk-Adjusted Reversion Rate

$$\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau)\tau^2 f(\nu(\lambda)\tau)^2 d\tau$$

- ν vs. λ : Consider a shock to short rate at time t
- Average change in short rate from t to $t + \tau$:

$$\frac{1}{\tau} E_t \left[\int_0^\tau \frac{\partial r_{t+u}}{\partial r_t} du \right]$$

Risk-Adjusted Reversion Rate

$$\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau)\tau^2 f(\nu(\lambda)\tau)^2 d\tau$$

- ν vs. λ : Consider a shock to short rate at time t
- Average change in short rate from t to $t + \tau$:

$$\frac{1}{\tau} E_t \left[\int_0^\tau \frac{\partial r_{t+u}}{\partial r_t} du \right] = \frac{1 - e^{-\lambda\tau}}{\lambda\tau} \equiv f(\lambda\tau)$$

Risk-Adjusted Reversion Rate

$$\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau) \tau^2 f(\nu(\lambda)\tau)^2 d\tau$$

- ν vs. λ : Consider a shock to short rate at time t
- Average change in short rate from t to $t + \tau$:

$$\begin{aligned} \frac{1}{\tau} E_t \left[\int_0^\tau \frac{\partial r_{t+u}}{\partial r_t} du \right] &= \frac{1 - e^{-\lambda\tau}}{\lambda\tau} \equiv f(\lambda\tau) \\ &\geq f(\nu\tau) \end{aligned}$$

Risk-Adjusted Reversion Rate

$$\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau) \tau^2 f(\nu(\lambda)\tau)^2 d\tau$$

- ν vs. λ : Consider a shock to short rate at time t
- Average change in short rate from t to $t + \tau$:

$$\begin{aligned} \frac{1}{\tau} E_t \left[\int_0^\tau \frac{\partial r_{t+u}}{\partial r_t} du \right] &= \frac{1 - e^{-\lambda\tau}}{\lambda\tau} \equiv f(\lambda\tau) \\ &\geq f(\nu\tau) \\ &= \frac{\partial R_{t,\tau}}{\partial r_t} \end{aligned}$$

which is the immediate response of τ -bond yields

Risk-Adjusted Reversion Rate

$$\nu(\lambda) = \lambda + a\sigma_r^2 \int_0^T \alpha(\tau)\tau^2 f(\nu(\lambda)\tau)^2 d\tau$$

- ν vs. λ : Consider a shock to short rate at time t
- Average change in short rate from t to $t + \tau$:

$$\begin{aligned} \frac{1}{\tau} E_t \left[\int_0^\tau \frac{\partial r_{t+u}}{\partial r_t} du \right] &= \frac{1 - e^{-\lambda\tau}}{\lambda\tau} \equiv f(\lambda\tau) \\ &\geq f(\nu\tau) \\ &= \frac{\partial R_{t,\tau}}{\partial r_t} \end{aligned}$$

which is the immediate response of τ -bond yields

- EH: two responses should be identical (only when $a = 0$)

General Equilibrium

Existence and Uniqueness

There exists a unique positive eigenvalue of Υ $\lambda_1 > 0$ for which $g(\lambda_1) = h(\lambda_1)$, which fully characterizes the model equilibrium. Further, this implies $0 < \hat{A}_r < 1$.

Conventional Policy and Financial Disruptions

Notes: equilibrium changes in sensitivity to the short rate \hat{A}_r as risk aversion a increases.

Conventional Policy and Financial Disruptions

Notes: equilibrium changes in monetary shock reversion λ_1 as risk aversion a increases.

Conventional Policy and Financial Disruptions

Notes: equilibrium changes in output response ω_x to monetary shocks as risk aversion a increases.

Policy Implications

- More aggressive response to output [\(\$\phi_x\$ results\)](#)
- Higher inertia [\(\$\kappa_r\$ results\)](#)
- Shifts in effective rate weights [\(\$\eta\(\tau\)\$ results\)](#)
- Forward guidance less effective as risk aversion increases [\(details\)](#)

Modeling LSAPs

- Suppose the central bank directly purchases bonds through open market operations
- Change to the demand shifter in PH demand

$$\tilde{b}_{t,\tau} = \alpha(\tau)\tau(R_{t,\tau} - \beta_{t,\tau})$$

Modeling LSAPs

- Suppose the central bank directly purchases bonds through open market operations
- Change to the demand shifter in PH demand

$$\tilde{b}_{t,\tau} = \alpha(\tau)\tau(R_{t,\tau} - \beta_{t,\tau})$$

$$\beta_{t,\tau} = \bar{\beta}(\tau) + \theta(\tau)\beta_t$$

$$d\beta_t = -\kappa_\beta \beta_t dt$$

Modeling LSAPs

- Suppose the central bank directly purchases bonds through open market operations
- Change to the demand shifter in PH demand

$$\tilde{b}_{t,\tau} = \alpha(\tau)\tau(R_{t,\tau} - \beta_{t,\tau})$$

$$\beta_{t,\tau} = \bar{\beta}(\tau) + \theta(\tau)\beta_t$$

$$d\beta_t = -\kappa_\beta \beta_t dt$$

Modeling LSAPs

- Suppose the central bank directly purchases bonds through open market operations
- Change to the demand shifter in PH demand

$$\tilde{b}_{t,\tau} = \alpha(\tau)\tau(R_{t,\tau} - \beta_{t,\tau})$$

$$\beta_{t,\tau} = \bar{\beta}(\tau) + \theta(\tau)\beta_t$$

$$d\beta_t = -\kappa_{\beta}\beta_t dt$$

Modeling LSAPs

- Change to the demand shifter in PH demand

$$\tilde{b}_{t,\tau} = \alpha(\tau)\tau(R_{t,\tau} - \beta_{t,\tau})$$

$$\beta_{t,\tau} = \bar{\beta}(\tau) + \theta(\tau)\beta_t$$

$$d\beta_t = -\kappa_\beta \beta_t dt$$

- Affine functional form of bond prices

$$-\log P_{t,\tau} = A_r(\tau)r_t + A_\beta(\tau)\beta_t + C(\tau)$$

$$\implies \tilde{r}_t = \hat{A}_r r_t + \hat{A}_\beta \beta_t + \hat{C}$$

Output Response to QE

Notes: plots of output gap response to a QE shock as risk aversion increases.

Output Response to QE

Notes: plots of output gap response to a QE shock as risk aversion increases.

Sticky Prices

- What about when prices are not fixed?

$$dx_t = \varsigma^{-1}(\tilde{r}_t - \pi_t - \bar{r}) dt$$

$$d\pi_t = (\rho\pi_t - \delta x_t) dt$$

$$dr_t = -\kappa_r(r_t - \phi_\pi\pi_t - \phi_x x_t - r^*) dt + \sigma_r dB_{r,t}$$

Sticky Prices

- What about when prices are not fixed?

$$dx_t = \varsigma^{-1}(\tilde{r}_t - \pi_t - \bar{r}) dt$$

$$d\pi_t = (\rho\pi_t - \delta x_t) dt$$

$$dr_t = -\kappa_r(r_t - \phi_\pi\pi_t - \phi_x x_t - r^*) dt + \sigma_r dB_{r,t}$$

- Results go through if determinacy condition is met:

$$\hat{A}_r > \frac{\delta}{\delta\phi_\pi + \rho\phi_x}$$

Sticky Prices

- What about when prices are not fixed?

$$dx_t = \varsigma^{-1}(\tilde{r}_t - \pi_t - \bar{r}) dt$$

$$d\pi_t = (\rho\pi_t - \delta x_t) dt$$

$$dr_t = -\kappa_r(r_t - \phi_\pi\pi_t - \phi_x x_t - r^*) dt + \sigma_r dB_{r,t}$$

- Results go through if determinacy condition is met:

$$\hat{A}_r > \frac{\delta}{\delta\phi_\pi + \rho\phi_x}$$

- If $\hat{A}_r = 1$ and $\phi_x = 0$, reduces to $\phi_\pi > 1$

Implications – Determinacy

Notes: determinacy condition as risk aversion a increases.

The model is determinate if the solid dark line lies above the dotted light line (light shaded region) and is indeterminate otherwise (dark shaded region).

Implications – Determinacy

Notes: determinacy condition as central bank response to inflation ϕ_π increases. The model is determinate if the solid dark line lies above the dotted light line (light shaded region) and is indeterminate otherwise (dark shaded region).

Implications – Determinacy

Notes: determinacy condition as central bank inertia κ_r increases.

The model is determinate if the solid dark line lies above the dotted light line (light shaded region) and is indeterminate otherwise (dark shaded region).

Quantitative (Generalized) Model

- Sticky price model with shocks

$$dx_t = \varsigma^{-1} (\tilde{r}_t - \pi_t - \bar{r} - z_{x,t}) dt$$

$$d\pi_t = (\rho\pi_t - \delta x_t - z_{\pi,t}) dt$$

$$dr_t = -\kappa_r(r_t - \phi_\pi\pi_t - \phi_x x_t - r^*) dt + \sigma_r dB_{r,t}$$

Quantitative (Generalized) Model

Notes: yield curve response to an “Operation Twist” shock on impact, for different levels of risk aversion α . Darker lines correspond to higher levels of risk aversion.

Yield Curve (Operation Twist)

Notes: yield curve response to an “Operation Twist” shock on impact, for different levels of risk aversion a . Darker lines correspond to higher levels of risk aversion.

Yield Curve (Operation Twist)

Notes: yield curve response to an “Operation Twist” shock on impact, for different levels of risk aversion α . Darker lines correspond to higher levels of risk aversion.

Yield Curve (Operation Twist)

Notes: yield curve response to an “Operation Twist” shock on impact, for different levels of risk aversion α . Darker lines correspond to higher levels of risk aversion.

Yield Curve (Operation Twist)

Notes: yield curve response to an “Operation Twist” shock on impact, for different levels of risk aversion α . Darker lines correspond to higher levels of risk aversion.

Yield Curve (Operation Twist)

Notes: yield curve response to an “Operation Twist” shock on impact, for different levels of risk aversion α . Darker lines correspond to higher levels of risk aversion.

Yield Curve (Operation Twist)

Notes: yield curve response to an "Operation Twist" shock on impact, for different levels of risk aversion α . Darker lines correspond to higher levels of risk aversion.

Yield Curve (Operation Twist)

Notes: yield curve response to an "Operation Twist" shock on impact, for different levels of risk aversion α . Darker lines correspond to higher levels of risk aversion.

Aggregate Response (Operation Twist)

Notes: inflation and output response an “Operation Twist” shock, for different levels of risk aversion α .

Optimal Conventional Policy

- Can the planner improve outcomes?
- Loss function

$$E_0 \int_0^{\infty} e^{-\rho t} (w_{\pi} \pi_t^2 + w_x x_t^2) dt$$

Optimal Conventional Policy

- Can the planner improve outcomes?
- Loss function

$$E_0 \int_0^{\infty} e^{-\rho t} (w_{\pi} \pi_t^2 + w_x x_t^2) dt$$

Optimal Conventional Policy

- Can the planner improve outcomes?
- Loss function

$$\min_{\phi_{\pi}, \kappa_r} E_0 \int_0^{\infty} e^{-\rho t} (w_{\pi} \pi_t^2 + w_x x_t^2) dt$$

- Optimal inflation response and inertia as financial disruptions increase conditional distribution

Optimal Response: More Aggressive in Crises

Notes: optimal policy coefficients on inflation (Panel A) and inertia (Panel B) as risk aversion increases. Planner weights: $w_\pi = 1$, $w_x = 0.1$.

Stabilizing LSAPs

- Can LSAPs be used to ensure determinacy?
- Endogenous QE purchases:

$$d\beta_t = -\kappa_\beta \left(\beta_t - \phi_\pi^\beta \pi_t \right) dt$$

Stabilizing LSAPs

- Can LSAPs be used to ensure determinacy?
- Endogenous QE purchases:

$$d\beta_t = -\kappa_\beta \left(\beta_t - \phi_\pi^\beta \pi_t \right) dt$$

QE and Determinacy

Notes: determinacy conditions as a function of risk aversion (x-axis) and endogenous response of QE to inflation (y-axis). Darker colors correspond to larger values of the unstable eigenvalue. The dotted black line demarcates the region of determinacy.

Concluding Remarks

- Develops a unified, parsimonious framework to study conventional and unconventional monetary policies
- Transmission depends crucially on the risk-bearing capacity of financial markets

Concluding Remarks

- Develops a unified, parsimonious framework to study conventional and unconventional monetary policies
- Transmission depends crucially on the risk-bearing capacity of financial markets
- Future work:
 - ▶ Macroprudential policies, default risk
 - ▶ Monetary policy in open economies
 - ▶ Debt management

APPENDIX

Phase Diagrams

Notes: phase diagrams of the dynamics of output and the policy rate as the equilibrium mean reversion rate of shocks varies.

Phase Diagrams

Notes: phase diagrams of the dynamics of output and the policy rate as the equilibrium mean reversion rate of shocks varies.

Phase Diagrams

Notes: phase diagrams of the dynamics of output and the policy rate as the equilibrium mean reversion rate of shocks varies.

Phase Diagrams

Notes: phase diagrams of the dynamics of output and the policy rate as the equilibrium mean reversion rate of shocks varies.

Implications – Conventional Policy

Notes: equilibrium changes in sensitivity to the short rate \hat{A}_r and monetary shock reversion λ_1 as central bank response to output ϕ_x increases.

[back](#)

Implications – Conventional Policy

Notes: equilibrium changes in sensitivity to the short rate \hat{A}_r and monetary shock reversion λ_1 as central bank inertia κ_r increases.

[back](#)

Sensitivity to Long Rates

Notes: different weighting function $\eta(\tau)$ in the determination of the effective borrowing rate \tilde{r}_t .

Sensitivity to Long Rates

Notes: different weighting function $\eta(\tau)$ in the determination of the effective borrowing rate \tilde{r}_t .

Implications – Sensitivity to Long Rates

Notes: equilibrium changes in sensitivity to the short rate \hat{A}_r and monetary shock reversion λ_1 as the weighting function $\eta(\tau)$ shifts towards short-term bonds.

[back](#)

Forward Guidance

- Central bank announces a peg: $r_0 = r^\diamond$ and

$$dr_t = \begin{cases} -\kappa_r^\diamond(r_t - r^\diamond)dt + \sigma_r^\diamond dB_{r,t} & \text{if } 0 < t < t^\diamond \\ -\kappa_r(r_t - \phi_x x_t - r^*)dt + \sigma_r dB_{r,t} & \text{if } t \geq t^\diamond \end{cases}$$

- Affine coefficient functions during peg:

$$\begin{aligned} -\log P_{t,\tau} &= A_r^\diamond(\tau)r_t + C^\diamond(\tau) \\ \implies \tilde{r}_t &= \hat{A}_r^\diamond r_t + \hat{C}^\diamond \end{aligned}$$

- Rational expectations dynamics for output:

$$\frac{\partial x_0}{\partial r^\diamond} = \omega_x - t^\diamond \varsigma^{-1} \hat{A}_r^\diamond, \quad \frac{\partial^2 x_0}{\partial r^\diamond \partial t^\diamond} = -\varsigma^{-1} \hat{A}_r^\diamond$$

Response to Forward Guidance

Notes: plots of $\frac{\partial x_0}{\partial r^\diamond}$ ("level") and $\frac{\partial^2 x_0}{\partial r^\diamond \partial t^\diamond}$ ("length") as risk aversion increases.

[back](#)

Long-Run Variance

- State-space representation

$$d\mathbf{y}_t = -\Gamma (\mathbf{y}_t - \mathbf{y}^{SS}) dt + \mathbf{S} d\mathbf{B}_t, \quad \mathbf{x}_t = \Omega (\mathbf{y}_t - \mathbf{y}^{SS})$$

- Conditional distribution $\mathbf{y}_t | \mathbf{y}_0 \sim N(\boldsymbol{\mu}_t, \boldsymbol{\Sigma}_t)$ where

$$\boldsymbol{\mu}_t = \mathbf{y}^{SS} + e^{-\Gamma t}(\mathbf{y}_0 - \mathbf{y}^{SS}), \quad \boldsymbol{\Sigma}_t = \int_0^t e^{\Gamma(u-t)} \boldsymbol{\Sigma} e^{\Gamma^T(u-t)} du$$

- Present-discounted value

$$\begin{aligned} \tilde{\boldsymbol{\Sigma}}_{\infty} &\equiv \int_0^{\infty} e^{-\rho t} \boldsymbol{\Sigma}_t dt \\ \implies \text{vec } \tilde{\boldsymbol{\Sigma}}_{\infty} &= (\Gamma \oplus \Gamma)^{-1} (\rho \mathbf{I} + \Gamma \oplus \Gamma)^{-1} \text{vec } \boldsymbol{\Sigma} \end{aligned}$$

- Jump variables

$$\tilde{\boldsymbol{\Sigma}}_{\infty}^{\mathbf{x}} = \Omega \tilde{\boldsymbol{\Sigma}}_{\infty} \Omega^T$$

Effective Borrowing Rate Weights

Notes: average maturity distribution of outstanding Treasury debt (light dotted line). The dark line corresponds to the effective borrowing rate weights in the model. Source: FRED.
